In probability theory, the birthday problem or birthday paradox concerns the probability that, in a set of  $n$  randomly chosen people, some pair of them will have the same birthday. By the pigeonhole principle, the probability reaches 100% when the number of people reaches 367 (since there are only 366 possible birthdays, including February 29). However, 99.9% probability is reached with just 70 ...

5c.If you need a “between-two-values” probability — that is,  $p(a < X < b)$  — do Steps 1–4 for  $b$  (the larger of the two values) and again for  $a$  (the smaller of the two values), and subtract the results. The probability that  $X$  is equal to any single value is 0 for any continuous random variable (like the normal). That’s because continuous random variables consider probability as being ...
